Thank you for employing the power regenerative converter MT-RC.

The equipment has been developed to improve the brake capacities of Mitsubishi Transistor Inverters (FR-A700, FR-F700, FR-A540L, FR-F540L, MT-A200, MT-A100, MT-A200E, MT-A100E, MT-V200 Series).

Before use, be sure to read through this instruction manual for proper operation.

* Don’t use the converter on any other inverter except described above since they can not be fit to each other.

Incorrect operation can cause the inverter to operate improperly, its life to be reduced considerably and in the worst case, the inverter to be damaged.
Please handle the inverter properly in accordance with the information in each section as well as the precautions and instructions of this manual.

- **Power supply**
  Use the power supply within the permissible power supply specifications of the inverter. (Refer to page 20)

- **Non-fuse breaker (NFB)** (Refer to page 7)
  Install NFB to supply power to the inverter and power regenerative converter together.

- **Reactors** (Refer to page 7, 9, 11)
  If any power cooperation is necessary, be sure to install the AC reactor on the power supply side. Since improper connecting method prevents the capacity from being fully shown or causes the power regenerative converter to be broken, take care for the installation position.

- **MT-RCL** (Refer to page 6)
  For installation of MT-RCL, refer to P6.
  When MT-RC is installed, it is surely necessary to install the AC reactor (MT-RCL).
  Connect it referring to the

- **Installation** (Refer to page 4)
  Since the ambient temperature largely influences the service life, use it at the position of the lowest possible temperature in the panel in order to prevent it from exceeding the tolerable value.

- **Wiring** (Refer to page 6)
  Improper wiring of the main circuit causes the product to be broken. Against the noise influence, separate the control signal line from the main circuit.
1 Structure

1-1 Appearance and structure

Fig. 1  Product appearance
2 Unpacking inspection

During unpacking inspection, check the following points.

(1) Checking the rating nameplate on the power regenerative converter, verify that the model is as ordered.
(2) Check for damage during transportation.
(3) Verify that the reactor model is as shown below.

|-----------------------------|------------|-------------|-------------|-------------|

If any obscure point or damage is found among the above, contact your dealer or our nearest sales office.
3 Installation

3-1 Transportation
Carefully handle the power regenerative converter against a damage. Here, don't lift it to apply any force to the surface cover alone.

3-2 Installation site
(1) For installation, avoid the following places.
Place exposed to direct sunlight, high temperature or high humidity. Place with oil mist, cotton or dust suspended. Place splashed with water, oil or grinding liquid. Place with falling iron powder. Place with corrosive gas. Place with inflammable gas. Place with vibration applied.

(2) When installing the power regenerative converter in the fully enclosed panel, check whether the cooling system and panel dimensions are sufficiently considered against heating of the converter itself or not.
In addition to the power regenerative converter, it is the important check point the ambient temperature of the inverter installed in the same panel is within the tolerance.

(3) For continuous regenerative operation with the converter installed in the panel, apply the method of Item 3-4.

3-3 Installation direction and space
(1) Securely install the converter on the play-free installation surface with the bolts to be vertical (the letters of the model MT-RC on the nameplate is visible from the front).

(2) Since the power regenerative converter generates heat, assure the sufficient surrounding space to prevent the heat from being accumulated.

(3) Don't arrange the power regenerative converter and inverter to vertical in line. (Otherwise, the warmed air will be sucked to cause overheating.)

Cautions for ambient temperature
Since the service life of the product is largely influenced by the ambient temperature, verify that the ambient temperature does not exceed the tolerable value (50°C) after installation in the position shown in the right.
3-4 Removal/installation of heat radiation fin section

If any regenerative state continues long in the winding operation, elevation operation and others in which a minus torque is applied for a long time, the power regenerative converter will generate much heat. If it is stored in the panel during such operation, the temperature in the panel will excessively rise. Therefore, it is recommended to install the power regenerative converter, exposing the heat radiation section outside as shown in Fig.2.

For this countermeasure, the installation leg can be replaced on the power regenerative converter MT-RC.

Preparation

- Produce the holes on the storage panel. For the machining hole dimensions, refer to P23 and P24.
- Reposition the installation leg (at two upper and lower places). Refer to Fig. 3.

![Diagram of panel installation](image)

**Fig. 2** Method to install the heat radiation section outside the panel

**Fig. 3** Reposition of installation leg

**Note:** The cooling fan is provided in the cooling section which is positioned outside the panel. Moreover, the section installed in the panel and the cooling section are not completely enclosed. Accordingly, don't use it in the poor environments of water drip, oil mist, dust, corrosive gas or similar.
4-1 Terminal connection diagram (The basic connection is shown.)

**CAUTION**

- When using either the FR-A700 series or FR-F700 series with the MT-RC, install a magnetic contactor (MC) at the input side of the inverter and power on the inverter 1s or more after powering on MT-RC. When power is supplied to the inverter before the MT-RC, the inverter and the MT-RC may be damaged or the MCCB may trip or be damaged.

<table>
<thead>

<td>1s or more</td>
</tr>
</tbody>
</table>
**Cautionary items for wiring**

(1) Properly connect the terminals P and N to the terminals P and N of the inverter. If they are improperly connected, the power regenerative converter will be broken.

![Proper connection](image1) ![Improper connection](image2)

(2) If the AC reactor MT-BAL for power cooperation is installed, be sure to connect it to the power supply side of the inverter. (Referring to P9, don't improperly connect them.)

(3) Keep the wiring distance of 5m or less across the terminals P and N of the inverter. Use the cables of the recommended size or more (Refer to P25).

(4) Though the common terminals SD and SE of the control circuit are insulated from each other, don't ground them.

(5) Use the shield cable or twist cable as the connection cables to the terminals of the control circuit, and separate them from the main circuit (power circuit, 200V sequence circuit and so on).

(6) To surely prevent the wire chips from entering the inside during wiring work, place the cover or similar on the upper vent hole.

(7) For secure grounding, use the ground terminal.

(8) Properly connect the terminals R, S and T in the phase order. If they are improperly connected, the power regenerative converter will be broken or the circuit breaker will trip against overcurrent. If it trips against overcurrent, be sure to check whether they are connected in the proper phase order or not before turning ON the power supply again.

**Design information**

(1) Arrange NFB and MC to surely make the power regenerative converter previously turned ON when the power supply is turned ON.

![Proper connection](image3) ![Improper connection](image4)

(2) Do not apply a large voltage to the contact input terminals (RES) of the control circuit.

(3) Do not apply a voltage directly to the alarm output signal terminals (A, B, C). Always apply a voltage to these terminals via a relay coil, lamp, etc.

(4) Since the input signals to the control circuit are on a low reveal, use two parallel micro signal contacts or a twin contact for contact inputs to prevent a contact fault.
4-2 Main circuit

(1) Connection of power supply and inverter

Power regenerative converter MT-RC

MT-RCL

Electromagnetic contactor (MC) [Note.1]

Non-fuse breaker (NFB)

Power regenerative converter MT-RC

Inverter

Motor

MT-RCL

Inverter

Non-fuse breaker (NFB)

[Note.1] Install the electromagnetic contactor on the inverter side alone. (If the power supply side of the power regenerative converter is opened during power regeneration, the power regenerative converter will sometimes be turned OFF due to overcurrent.)

(2) Connection of power supply of control circuit to another power supply

If MC of the power supply is turned OFF when the protective circuit is activated, the power supply of the control circuit will be turned OFF to make it impossible to hold the error signal (relay) and error indication. If it is necessary to hold them, proceed with the following procedure to connect the power supply of the control circuit to another power supply or the primary side of MC.
(3) Connection of AC reactor to the power side
Don't install the power cooperation type AC reactor (MT-BAL) on the power supply side of MT-RCL. When MT-BAL is installed, apply the following connection.

(4) Connection of power-factor improving DC reactor provided on the inverter (Connection to the terminals P thru P1 of the inverter)
For connection, be sure to use the DC reactor which is provided on the inverter.
Connect the terminals P and N of the power regenerative converter to the terminals P and N of the inverter, and the terminals U and X of DCL to the terminals P1 and P without mistake. (Refer to the following figure.)
4-3 Control circuit

(1) Input signal

(2) Output signal

Abnormal output
(1C contact output)

Ready output
(Open collector output)

---

Cautionary items for connection to sequencer

If the control power voltage in the inverter becomes higher than the external power voltage of the sequencer when the sequencer output unit (open collector output) and MT-RC are connected, the dot-lined current will flow to give the command signal to the inverter even though the transistor of the sequencer is not turned ON.

Countermeasure

(1) Insert the diode which prevents the sneak current.

(2) Use the output unit of all-point independent type. (Example: AY40A, etc.)

(3) The external power supply becomes higher than the control power supply of the power regenerative converter.
4-4 Connection example

(1) Combination of brake motor and power regenerative converter (*MT-RC*) (Application for elevation equipment and so on)
- In combination with the brake motor, it is also applicable for the elevator equipment. It is used in combination with MT-RC type power regenerative converter.
- Since it sometimes slips down on the elevation equipment at the start time, it is necessary to delay the release timing of the brake. Against such a case, the brake is released with the frequency arrival signal (FU).

![Diagram of output frequency and brake release](image)

**Note 1:** The AC reactor (*MT-BAL*) for power cooperation is necessary in the following cases.
- The ratio between power capacity and inverter capacity is 10 times or more
- The rectifier load is present in the same power supply.
- The phase-advance capacitor is present in the same power supply.

**Note 2:** The terminals STF and SD of the power generative converter (*MT-RC*) is normally short-circuited.

**Note 3:** LS indicates the upper/lower limit switch of the machine.

**Note 4:** MC1X is the auxiliary contact of the contactor MC1.

**Note 5:** Be sure to separate the SD terminals of the inverter unit and power regenerative converter from each other.

5 Operation

5-1 Inspection before operation

After installation and wiring, check the following before turning ON the power supply.

1. Is any error present in the wiring? Is it properly wired particularly on the terminals P and N of the main circuit?

2. Is any wire chip left inside after the cable connecting work? Is it also short-circuited with wire chip or similar?

3. Is it skipped to fasten any terminal screw, or it is loose?

4. Check the phase order of the power supply, and verify that any wrong connection is not present on the power terminals R2, S2 and T2, and the phase power terminal R, S and T.

Options:

- Set the parameters of the inverter to make the power regeneration possible.
  - Set “1” at Pr. 30. (Regenerative operation is selected.)
  - Set “100” at Pr. 70. (Set the operation rate% ED. Be sure to set “100” when MT-RC is used.)
  - Set the motor rating at Pr. 3 and 19. (Excessive excitation is prevented during regeneration.)

5-2 Operation example (Case of load with power running during acceleration and constant speed and regeneration during deceleration)

Preparation

- Turn OFF the start signal of the inverter.
- Zero the signal of the frequency command of the inverter.

<table>
<thead>
<tr>
<th>Power supply ON</th>
<th>Turn ON NFB and MC.</th>
<th>LED lamp on the unit is lit.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Start</td>
<td>Turn ON the operation signal of the inverter.</td>
<td>The cooling fan starts running.</td>
</tr>
<tr>
<td>Acceleration</td>
<td>Gradually increase the frequency command of the inverter to the max. speed.</td>
<td>The ready signal is turned ON.</td>
</tr>
<tr>
<td>Deceleration</td>
<td>Turn OFF the operation signal of the inverter.</td>
<td>The revolution speed of the motor is increased to the constant speed.</td>
</tr>
</tbody>
</table>

Check point

- Does the regenerative power LED indicate any proper value? Since the regenerative operation may not be proper, check the wiring and the constant setting value for the inverter.
- Does the regenerative power indication exceed 100%? If this state continues long, it may trip since the capacity is exceeded.
  - The regenerative power indicator (% indication) includes an error of approx. 5%.
- Is the trouble indicator lit? Referring to Item "Protective function", inspect the cause.
6 Precautions for maintenance

The transistorized inverter is a static unit mainly consisting of semiconductor devices. Daily inspection must be performed to prevent any fault from occurring due to adverse influence by the operating environment, such as temperature, humidity, dust, dirt and vibration, changes in the parts with time, service life, and other factors.

6-1 Precautions for maintenance and inspection

Even after the power is shut down, high voltage is charged on the inner electrolytic capacitor for a while. For the inspection, turn OFF the power supply, and wait until the charge lamp on the control board goes out. Using the tester or similar, verify that DC voltage across the terminals P and N is 0V.

6-2 Check items

(1) Daily inspections

Check the following:
- Motor operation fault
- Unusual vibration and noise
- Unusual overheating and discoloration
- Cleaning of filter in the vent section of storage panel
- Improper installation environment

(2) Periodic inspection

Check the areas inaccessible during operation and requiring periodic inspection. For periodic inspection, consult us.
- Screws and bolts
- Conductors and insulating materials: Check for corrosion and damage.
- Cooling fan, smoothing capacitor, relay: Check and change if necessary.
- Cooling system fault

(3) Megger test procedure

- Before the megger test of the power system, disconnect the cable which is connected to the power regenerative converter, in order to prevent the test voltage from being applied.
- Take the megger test of the power regenerative converter itself, keeping the terminal block of the main circuit short-circuited with the procedure in Fig. 4. Here, don't take the megger test of the control circuit.

Note 1: When taking the continuity test of the control circuit, use the tester (in the high-resistance range) but not the megger buzzer.

![Megger test procedure](image)

6-3 Checking the inverter and converter modules

(1) Preparation
- Disconnect the external power supply cables (R2, S2 and T2) and inverter cables (P, N).
- Prepare a tester. (Use 1Ω range.)

(2) Checking method
Change the polarity of the tester alternately at the inverter terminals R2, S2, T2, P and N, check for continuity.

Note: 1. Before measurement, check that the smoothing capacitor is discharged.
2. At the time of continuity, the measured value is several to several ten’s-of ohms depending on the module type, quantity in parallel, circuit tester type, etc. If all measured values are almost the same, the modules are without fault.

On the model in which plural modules are connected in parallel, it is necessary to disconnect the connection bus cable in order to isolate the defective module.

Module device numbers and terminals to be checked
6-4 Replacement of parts

The inverter consists of many electronic parts such as semiconductor devices. The following parts may deteriorate with age because of their structures or physical characteristics, leading to reduced performance or failure of the inverter. For preventive maintenance, the parts must be changed periodically.

(1) Cooling fan
The cooling fan cools heat-generating parts such as the main circuit semiconductor devices. The life of the cooling fan bearing is usually 10,000 to 35,000 hours. Hence, the cooling fan must be changed every 2 to 3 years if the inverter is run continuously. When unusual noise and/or vibration is noticed during inspection, the cooling fan must be changed immediately.

(2) Smoothing capacitors
A large-capacity aluminum electrolytic capacitor is used for smoothing the DC in the main circuit, and an aluminum electrolytic capacitor is also used for stabilizing the control power in the control circuit. Their characteristics are adversely affected by ripple current, etc. When the inverter is operated in an ordinary, air-conditioned environment, change the capacitors about every 5 years. When 5 years have elapsed, the capacitors will deteriorate more rapidly.
Check the capacitors at least every year (less than six months if their life will be expired soon).
Check the following:
1) Case (side faces and bottom face for expansion)
2) Sealing plate (for remarkable warping and extreme cracks)
3) Explosion-proof valve (for excessive valve expansion and operation)
4) Appearance, external cracks, discoloration, leakage. When the measured capacitance of the capacitor has reduced below 85% of the rating, change the capacitor.
   (On the new part, measure and record the capacity across P and N.)

(3) Relays
To prevent a contact fault, etc., relays must be changed according to the number of accumulative switching times (switching life).
See the following table for the inverter parts replacement guide. Lamps and other short-life parts must also be changed during periodic inspection.

9-1 Selection of peripheral equipment

(1) Referring to "Instruction Manual for Inverter", select the non-fuse breaker (NFB) and electromagnetic contactor (MC) depending on the capacities of the motor and inverter.

(2) On the connection cables to the power regenerative converter, select the cable size (mm²) which is larger than specified in the following table.

<table>
<thead>
<tr>
<th>Model MT-RC</th>
<th>Applicable motor capacity (kW)</th>
<th>Cable size</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>R2/S2/T2</td>

<tr>
<td>MT-RC-H280K</td>
<td>280</td>
<td>2x125</td>
</tr>
</tbody>
</table>

The table is based on the characteristics of the standard motors of Mitsubishi Electric Corp..

(3) Select MT-BSL and MT-BAL according to the capacity of the inverter.

(4) Since MT-RCL is attached to MT-RC, be sure to use the attached one.

9-2 Model selection

According to the motor capacity and brake torque strength, select the model as shown in the following table.

- Don't use MT-RC whose capacity is larger than combined in the following table.
  (Even if the capacity of MT-RC is increased, the continuous brake torque will not exceed 100% of the motor rating.)

Brake torque (%) for continuous rating (% with the rated torque of the motor regarded as 100%)

Instruction Manual Supplement

Instruction for control power supply terminals

When the control power supply voltage is 441 VAC or higher, remove the jumper on the control power supply terminal block as shown below. If not removed, the unit could be damaged.
